

# Introduction to SQL

- The learning objectives for this week are:
  - Knowing how to use **SQL Server Management Studio** to connect to the SQL Server RDBMS
  - Knowing how to use SQL Server Management Studio to execute database queries
  - Knowing how to create database tables using SQL
  - Knowing how to insert data into a table using SQL
  - Knowing how to retrieve data from the database using SQL

# SQL

- **Structured Query Language** (SQL) is the standard database language for relational databases
- With SQL we can, create the database and table structures, manipulate data in the tables (insert, update, delete) and retrieve data from the tables
- An **SQL query** is a single statement in which describes what we want from the database
- The query operates on **tables** and builds a result table from one or more tables in the database

```
SELECT teacher_number, email, phone  
FROM Teacher  
WHERE first_name = 'John' AND surname = 'Doe';
```

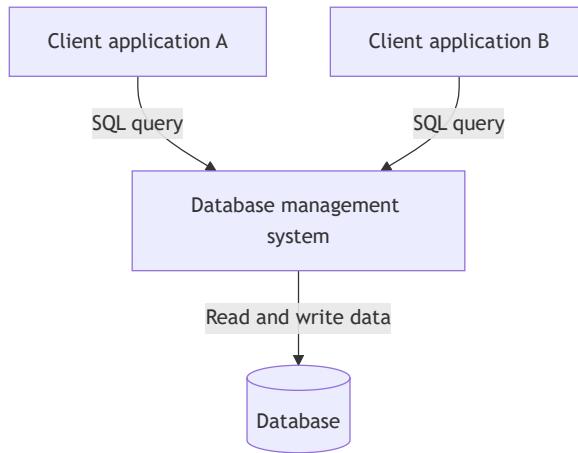

teacher_number	email	phone
T254	john.doe@haaga-helia.fi	(415) 555-0198

# SQL syntax variations

- There is an official standard for SQL maintained by ISO/IEC and **most of the syntax is the same in all RDBMS**, but **every major RDBMS introduces its own extensions, syntax tweaks, or behaviors**
- However, learning the SQL syntax of a specific RDMBS makes it very easy to learn the minor differences of another one

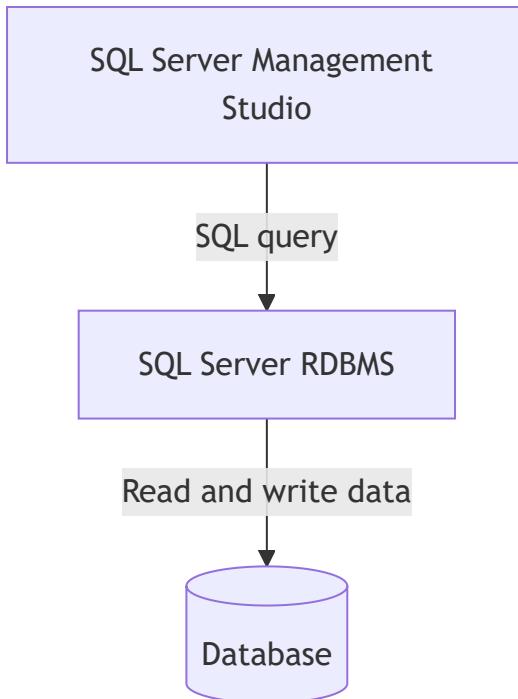

Operation	SQL Server	PostgreSQL
Limit rows	<code>SELECT TOP 5 * FROM table</code>	<code>SELECT * FROM table LIMIT 5</code>
Current datetime	<code>GETDATE()</code>	<code>NOW()</code>
String length	<code>LEN(string)</code>	<code>LENGTH(string)</code>

# Communicating with a RDBMS using SQL

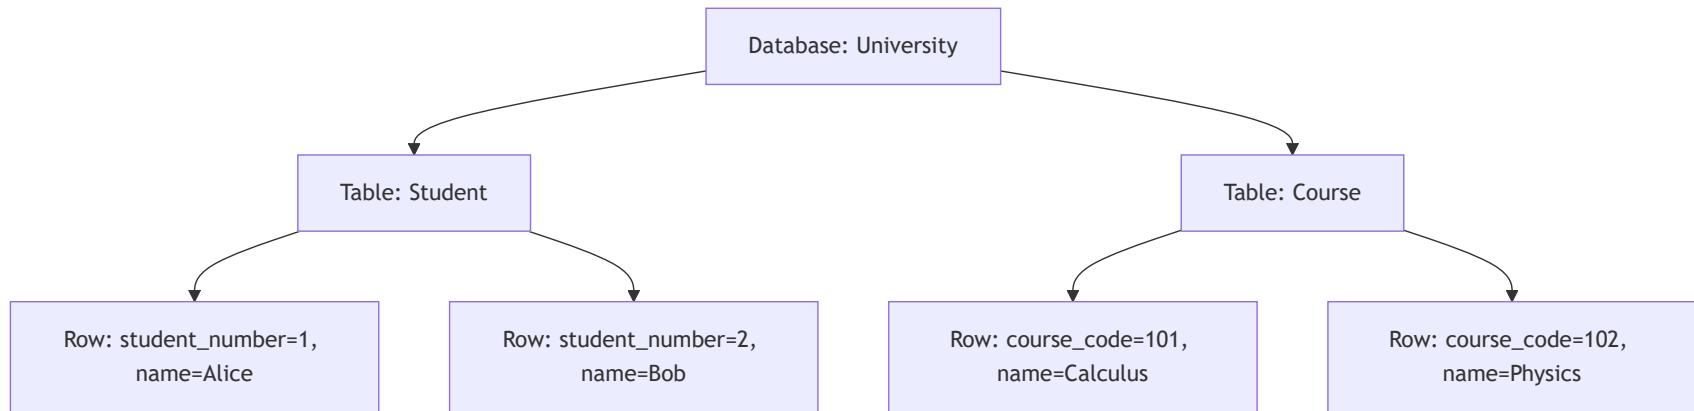

- SQL is used with a relational database management systems (RDBMS), such as **Microsoft SQL Server**, which we will be using during the course
- RDBMS software can be running on local computer on a server on the internet
- We can send database queries to a RDBMS using a **client application**, which can be, for example a programming interface, a command line interface or a graphical interface
- During the course we have the option to either install the SQL Server on our computer or use the SQL server running in Haaga-Helia's servers

# Communicating with a RDBMS

- During this course we will be using a graphical interface called **SQL Server Management Studio** to communicate with the SQL Server RDBMS
- With SQL Server Management Studio we can for example inspect and manage database related information, perform database queries and visualize the structure of the database tables

# Creating a database

- In SQL, a **database** is a named collection of **tables**
- In addition to tables, database holds different kinds of configuration, for example related to access control
- We can create a database with the `CREATE DATABASE` statement

```
CREATE DATABASE University
```

# Creating a table

- The actual data of a database lives inside **tables**
- Table has a name and a collection of **columns**
- We can create a table with the `CREATE TABLE` statement

```
CREATE TABLE Student (
    student_number INTEGER,
    first_name VARCHAR(50),
    surname VARCHAR(50)
)
```

student_number	first_name	surname
1001	Alice	Johnson
1002	Bob	Smith
1003	Charlie	Nguyen

# Creating a table

- Table and column names **should describe the information they store**
  - The "Student" table contains rows that represent students
  - The "first\_name" column contains the first name of the student
- Table and column names should consist of letters, digits or underscores. They **should not contain whitespace**
- In column names, a underscore symbol (\_) is commonly used instead of whitespace. For example "first\_name" instead of "first name"
- Table names are commonly in **singular format**, for example "Student"
- Each column has a **data-type** that determines the kind of values the column can have
- For example an `INTEGER` type of column can only contain integer values and `VARCHAR(n)` column string values

# SQL Server data types

Category	Data Type	Description
Integer Types	INT	Integer from -2,147,483,648 to 2,147,483,647
	BIGINT	Integer from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807
Decimal Types	DECIMAL(p,s)	Fixed precision and scale numeric data
Character Types	CHAR(n)	Fixed-length non-Unicode string (max 8,000 chars)
	VARCHAR(n)	Variable-length non-Unicode string
Unicode Types	NCHAR(n)	Fixed-length Unicode string
	NVARCHAR(n)	Variable-length Unicode string
Date & Time	DATE	Stores date (YYYY-MM-DD)
	TIME	Stores time only (HH:MM:SS)

# Constraints

- **Constraints** specify rules for the data in a table
- For example `NOT NULL` constraint ensures that a column cannot have a `NULL` (empty) value
- The `NOT NULL` constraint is defined **after the column type** in the `CREATE TABLE` statement

```
CREATE TABLE Student (
    student_number INTEGER NOT NULL,
    first_name VARCHAR(50) NOT NULL,
    surname VARCHAR(50) NOT NULL
)
```

# Primary key constraint

- **Primary key** uniquely identifies each row in the table
- **Primary key constraint** prevents duplicate rows to exist for the table
- Primary key constraint is defined with the `PRIMARY KEY` constraint **after the column definitions** in the `CREATE TABLE` statement

```
CREATE TABLE Student (
    student_number INTEGER NOT NULL,
    first_name VARCHAR(50) NOT NULL,
    surname VARCHAR(50) NOT NULL,
    -- the primary key is the student_number column
    CONSTRAINT Pk_Student PRIMARY KEY (student_number)
)
```

# Foreign key constraint

- **Foreign key** is a column or group columns whose values are required to match those of the primary key of the referenced table
- **Foreign key constraint** prevents foreign key not being matched by a primary key in the referenced table
- Foreign key constraint is defined with the `FOREIGN KEY` constraint **after the column definitions** in the `CREATE TABLE` statement

```
CREATE TABLE Laptop (
    serial_number VARCHAR(10) NOT NULL,
    student_number INTEGER NOT NULL,
    -- the primary key is the serial_number column
    CONSTRAINT Pk_Laptop PRIMARY KEY (serial_number),
    -- the foreign key student_number references the student_number in the Student table
    CONSTRAINT Fk_Student FOREIGN KEY (student_number)
        REFERENCES Student(student_number)
)
```

# Inserting data

- We insert a new row into a table by defining the table name and the values for the columns
- A new row can be inserted with the `INSERT INTO` statement
-  String literals are defined with **single quotes**, for example `'Kalle'`

```
INSERT INTO Student (student_number, first_name, surname) VALUES (1, 'Kalle', 'Ilves')
```

# Constraint violations while inserting data

- Constraints are checked once a new row is inserted or updated
- If there are any constraint violations, **the new row won't be inserted**
- For example if `NOT NULL` constraint of a column is violated, there will be an error

```
-- ❌ surname columns has a NOT NULL constraint, omitting it will cause an error
INSERT INTO Student (student_number, first_name) VALUES (1, 'Kalle')
```

# Retrieving data

- The `SELECT` statement is used to select rows from a table
- With the `SELECT` statement we define a group of columns we want to select the data from and the name of the target table
- The result is a **result table** containing the rows from the target table with the specified columns

```
SELECT first_name, surname FROM Student
```

first_name	surname
Alice	Johnson
Bob	Smith
Charlie	Nguyen

# Summary

- We communicate with a **RDBMS server**, such as SQL Server using a **client application**, such as SQL Server Management Studio
- We can create database tables using the `CREATE TABLE` statement
- `PRIMARY KEY` constraint is used to define the table's primary key
- `FOREIGN KEY` constraint is used to define a foreign key referencing primary key column of another table
- `INSERT INTO` statement is used to insert a new row for the table
- `SELECT` statement is used to select rows from a table
